## [1240]

Observations of Dr Papin, Fellow of the Royal Society, on a French Paper concerning a Perpetual Motion.

HE Paper printed in French and containing a contrivance for a perpetual motion, being fet down in such a manner, that can hardly be understood but by those that are much acquainted with such descriptions: I have endeavour'd to explain it as follow's.

Let DEF Fig. 9. be a pair of bellow's 40 inches long, that may be open'd by removing the part F from E: let them be exactly flut every where but at the aperture E; and let a pipe EG, 20 or 22 inches long, be foddered to the fay'd aperture E, having its other end in a Vessel G, full of Mercury, and placed near the middle of the bellow's.

A, Is an axis for the bellow's to turn upon.

B, A counterpoise fastened to the lower end of the bellows.

C, A weight with a class to keep the bellow's upright. Now if we suppose the bellow's open'd only to \frac{1}{3} or \frac{1}{6} standing upwright as Fig. 9th. and full of Mercury, it is plain that the fayd Mercury being 40 inches high, must fall, as in the Torricellian experiment, to the height of about 27 inches, and consequently the bellow's must open towards F and leave a vacuity there: this vacuity must be fill'd with the Mercury ascending from G through the Pipe GE, the fayd Pipe being but 22 inches long: by this means the bellow's must be opened more and more till the Mercury continuing to ascend make's the upper part of the bellow's so heavy, that the lower part must get loofe from the clasp C, and the bellow's should turn quite upfide down; but the Vessel G being set in a convenient place keeps them horizontall as Fig. 10, and the part

part F engageth there in another Class C; then the Mercury by its weight runs out from the bellows into the Vessel G through the Pipe EG, and the bellow's must shut closer and closer untill the part EF comes to be so light, that the counterpoise B is able to make the part F get loose from the class C; then the bellow's come to be upright again as Fig. 9th; the Mercury lest in them fall's again to the height of 27 inches, and consequently all the other effects will follow as we have already seen, and the motion will continue for ever. Thus much the French Author.

Upon this it is to be observed, that the bellow's can never be opened by the internal pressure, unless the sayd pressure be stronger then the externall: now in this case the weight of the Atmosphere doth freely press upthe outward part of the bellow's, but it cannot come at the inward part but through the Pipe GE, which containing 22 perpendicular inches of Mercury, doth counterpoise so much of the weight of the Atmosphere, so that this being supposed to be 27 inches of Mercury, it cannot press the inward part of the bellow's but with a weight equivalent to 5 perpendicular inches of Mercury. From this we may conclude, that the pressure of the Atmosphere being weakned within the bellow's, more then it can be helpt by the Mercury contain'd in the same, as may eafily be computed; the fayd bellow's standing upright as Fig. 9th; must rather shut then open. Thus, without loofing any labour and charges in trying, people may be fure that the thing can never do.

Philosoph. Transact. Wumb. 177.
